PROVISIONAL SPECIFICATION

Invention Title:

Antifungal peptides

The invention is described in the following statement:

ANTIFUNGAL PEPTIDES

FIELD OF THE INVENTION

The present invention relates to antifungal peptides, especially antifungal peptides obtained from insect species, particularly lepidopterans. The present invention also provides methods of using these antifungal peptides to treat or prevent fungal growth for a variety of purposes such as; protecting plants from fungal infections, treating fungal infections of animals, especially humans, and prevention of food spoilage.

BACKGROUND OF THE INVENTION

Fungi are eukaryotic cells that may reproduce sexually or asexually and may be biphasic, with one form in nature and a different form in the infected host. Fungal infections of plants and animals are a significant problem in the fields of agriculture, medicine and food production/storage. Fungal infections are becoming a major concern for a number of reasons, including the limited number of antifungal agents available, the increasing incidence of species resistant to older antifungal agents, and the growing population of immunocompromised patients at risk for opportunistic fungal infections.

Fungal diseases of humans are referred to as mycoses. Some mycoses are endemic, where infection is acquired in the geographic area that is the natural habitat of that fungus. These endemic mycoses are usually self-limited and minimally symptomatic. Some mycoses are chiefly opportunistic, occurring in immunocompromised patients such as organ transplant patients, cancer patients undergoing chemotherapy, burn patients, AIDS patients, or patients with diabetic ketoacidosis.

Fungi cause many diseases of plants such as, but not limited to, mildews, rots, rusts, smuts, and wilts etc. For example, soilborne fungal phytopathogens cause enormous economic losses in the agricultural and horticultural industries. In particular, *Rhizoctonia solani* is one of the major fungal phytopathogens exhibiting strong pathogenicity; it is associated with seedling diseases as well as foliar diseases such as seed rot, root rot, damping-off, leaf and stem rot of many plant species and varieties, resulting in enormous economic losses. Another example is *Phytophthora capsici* which is a widespread and highly destructive soilborne fungal phytopathogen that causes root and crown rot as well as the aerial blight of leaves, fruit, and the stems of peppers (*Capsicum annuum* L.).

Plant fungus infection is a particular problem in damp climates and may become a major concern during crop storage. Plants have developed a certain degree of natural

resistance to pathogenic fungi; however, modern growing methods, harvesting and storage systems frequently provide a favorable environment for plant pathogens.

Antifungal agents include polyene derivatives, such as amphotericin B and the structurally related compounds nystatin and pimaricin. Furthermore, antifungal peptides have been isolated from a variety of naturally occurring sources (DeLucca and Walsh, 1999). However, there is a need for the identification of further compounds with antifungal activity for use in medical, agricultural and industrial related applications to control and/or prevent fungal growth.

SUMMARY OF THE INVENTION

The present inventors have isolated and characterized new antifungal peptides. Accordingly, in a first aspect the present invention provides a substantially purified peptide which comprises a sequence selected from the group consisting of:

i) an amino acid sequence as provided in SEQ ID NO:4,

ii) an amino acid sequence which is at least 70% identical to SEQ ID NO:4,

iii) an amino acid sequence as provided in SEQ ID NO:5,

iv) an amino acid sequence which is at least 80% identical to SEQ ID NO:5,

v) a biologically active fragment of any one of i) to iv), and

vi) a precursor comprising the amino acid sequence according to any one of i) to v),

wherein the peptide, or fragment thereof, exhibits antifungal activity.

In a preferred embodiment of the first aspect, the peptide is at least 80%, more preferably at least 85%, more preferably at least 90%, more preferably at least 92%, more preferably at least 95%, more preferably at least 97%, and even more preferably at least 99% identical to the sequence provided in SEQ ID NO:4.

In a further preferred embodiment, the peptide is at least 85%, more preferably at least 90%, more preferably at least 92%, more preferably at least 95%, more preferably at least 97%, and even more preferably at least 99% identical to the sequence provided in SEQ ID NO:5.

Preferably, the precursor of SEQ ID NO:4 is SEQ ID NO:1 or SEQ ID NO:2, and the precursor of SEQ ID NO:5 is SEQ ID NO:3.

Preferably, the peptide can be purified from an insect. More preferably, the peptide can be purified from a lepidopteran insect. More preferably, the peptide can be purified from a lepidopteran insect of the family Pyralidae. More preferably, the peptide can be purified from a *Galleria sp.*

In a particularly preferred embodiment, the peptide can be purified from an insect which has been exposed to a fungal or bacterial infection. In the case of lepidpoterans, it is preferred that the peptide can be purified from last instar larvae that

have been exposed to bacteria such as, but not limited to, *Escherichia coli* and/or *Micrococcus luteus*.

In another embodiment, it is preferred that the peptide has a molecular weight of between about 4.5 kDa to about 3.3 kDa. More preferably, the peptide has a molecular weight of about 4.3 kDa or about 3.6 kDa.

Preferably, the peptide exhibits antifungal activity against the Family of fungi selected from, but not limited to, the group consisting of: Nectriaceae, Pleosporaceae, Mycosphaerellaceae, Phyllachoraceae, Leptosphaeria, and Trichocomaceae. More preferably, the peptide exhibits antifungal activity against the Genera of fungi selected from, but not limited to, the group consisting of: Fusarium (also known in the art as Gibberella), Alternaria, Ascochyta, Colletotrichum, Leptosphaeria and Aspergillus. In a particularly preferred embodiment, the peptide exhibits antifungal activity against the Genera of fungi which infect plants selected from, but not limited to, the group consisting of: Alternaria; Ascochyta; Botrytis; Cercospora; Colletotrichum; Diplodia; Erysiphe; Fusarium; Gaeumanomyces; Helminthosporium; Leptosphaeria, Macrophomina; Nectria; Peronospora; Phoma; Phymatotrichum; Phytophthora; Plasmopara; Podosphaera; Puccinia; Puthium; Pyrenophora; Pyricularia; Pythium; Rhizoctonia; Scerotium; Sclerotinia; Septoria; Thielaviopsis; Uncinula; Venturia; and Verticillium. In a further preferred embodiment, the peptide exhibits antifungal activity against the fungi selected from the group consisting of: *Fusarium graminearum*, *Alternaria alternata*, *Ascochyta rabiei*, *Colletotrichum gloeosporioides*, *Leptosphaeria maculans* and *Aspergillus niger*.

In a further aspect, the present invention provides a fusion protein comprising a peptide according to the invention fused to at least one other polypeptide/peptide sequence.

In a preferred embodiment, the at least one other polypeptide/peptide is selected from the group consisting of: a polypeptide/peptide that enhances the stability of a peptide of the present invention, a polypeptide/peptide that assists in the purification of the fusion protein, a polypeptide/peptide which assists in the peptide of the invention being secreted from a cell (particularly a plant cell), and a polypeptide/peptide which renders the fusion protein non-toxic to a fungus or a bacteria but which can be processed, for example by proteolytic cleavage, to produce an antifungal peptide of the invention.

In another aspect, the present invention provides an isolated polynucleotide, the polynucleotide comprising a sequence selected from:

(i) a sequence of nucleotides provided in SEQ ID NO:9 or SEQ ID NO:10;

(ii) a sequence of nucleotides provided in SEQ ID NO:11;

(iii) a sequence of nucleotides provided in SEQ ID NO:12;

(iv) a sequence of nucleotides provided in SEQ ID NO:13;

(v) a sequence encoding a polypeptide according to the first aspect;

(vi) a sequence of nucleotides which is at least 70% identical to SEQ ID NO:9, SEQ ID NO:10, or SEQ ID NO:12;

(vii) a sequence of nucleotides which is at least 80% identical to SEQ ID NO:11 or SEQ ID NO:13; and

(viii) a sequence which hybridizes to any one of (i) to (iv) under high stringency conditions.

Preferably, the polynucleotide encodes a peptide with antifungal activity.

In a preferred embodiment, the polynucleotide is at least 80%, more preferably at least 85%, more preferably at least 90%, more preferably at least 92%, more preferably at least 95%, more preferably at least 97%, and even more preferably at least 99% identical to SEQ ID NO: 9, SEQ ID NO:10 or SEQ ID NO:12.

In a preferred embodiment, the polynucleotide is at least 85%, more preferably at least 90%, more preferably at least 92%, more preferably at least 95%, more preferably at least 97%, and even more preferably at least 99% identical to SEQ ID NO:11 or SEQ ID NO:13.

Preferably, the polynucleotide can be isolated from an insect. More preferably, the polynucleotide can be isolated from a lepidopteran insect. More preferably, the polynucleotide can be isolated from lepidopteran insect of the family Pyralidae. More preferably, the polynucleotide can be isolated from a *Galleria sp.*

In another embodiment, the polynucleotide comprises a sequence provided as SEQ ID NO:6, SEQ ID NO:7 or SEQ ID NO:8.

Also provided is a polynucleotide encoding a fusion protein of the invention.

Furthermore, the present invention provides a suitable vector for the replication and/or expression of a polynucleotide according to the invention. Thus, also provided is a vector comprising a polynucleotide of the invention.

The vectors may be, for example, a plasmid, virus, transposon or phage vector provided with an origin of replication, and preferably a promotor for the expression of the polynucleotide and optionally a regulator of the promotor. The vector may contain one or more selectable markers, for example an ampicillin resistance gene in the case of a bacterial plasmid or a neomycin resistance gene for a mammalian expression vector. The vector may be used *in vitro*, for example for the production of RNA or used to transfect or transform a host cell.

In another aspect the present invention provides a host cell comprising a vector of the invention.

Preferably, the host cell is an animal, yeast, bacterial or plant cell. More preferably, host cell is a plant cell.

In a further aspect, the present invention provides a process for preparing a peptide according to the first aspect, the process comprising cultivating a host cell according to the invention under conditions which allow expression of the polynucleotide encoding the peptide, and recovering the expressed peptide.

The present invention also provides peptides produced by a process of the invention.

In a further aspect, the present invention provides a composition comprising a peptide, a polynucleotide, a vector, an antibody or a host cell of the invention, and one or more acceptable carriers.

In an embodiment, the carrier is a pharmaceutically, veterinary or agriculturally acceptable carrier.

In yet another aspect, the present invention provides a method for killing, or inhibiting the growth and/or reproduction of a fungus, the method comprising exposing the fungus to a peptide of the invention.

As the skilled addressee would be aware, the fungus can be exposed to the peptide by any means known in the art. In one embodiment, the fungus is exposed to a composition comprising the peptide. In another embodiment, the fungus is exposed to a host cell producing the peptide.

Plants and non-human animals resistant to fungal infections can be produced by introducing a polynucleotide of the invention into the plant or animal such that the peptide is produced in the transgenic organism.

Accordingly, in another aspect, the present invention provides a transgenic plant, the plant having been transformed with a polynucleotide according to the present invention, wherein the plant produces a peptide of the invention.

The transgenic plant can be any species of plant, however, it is preferred that the plant is a crop plant. Examples of such crop plants include, but are not limited to, wheat, barley, rice, chickpeas, field peas and the like.

In a further aspect, the present invention provides a method of controlling fungal infections of a crop, the method comprising cultivating a crop of transgenic plants of the invention.

In addition, in another aspect, the present invention provides a transgenic non-human animal, the animal having been transformed with a polynucleotide according to the present invention, wherein the animal produces a peptide of the invention.

In a further aspect, the present invention provides a method of treating or preventing a fungal infection in a patient, the method comprising administering to the patient a peptide of the invention.

In addition, the present invention provides for the use of a peptide of the invention for the manufacture of a medicament for treating or preventing a fungal infection in a patient.

Also provided is an antibody which specifically binds a peptide of the first aspect. Such antibodies will be useful as markers for peptide production from transgenic systems such as transgenic plants. In addition, such antibodies may be useful in methods of purifying peptides of the invention from insect lysates and/or recombinant expression systems.

It is envisaged by the present inventors that the peptides of the invention also exhibit antibacterial activity. Thus, the present invention also provides a method for killing, or inhibiting the growth and/or reproduction of a bacteria, the method comprising exposing the bacteria to a peptide of the invention.

The bacteria can be gram-positive or gram-negative. Preferably, the bacteria is a gram-positive bacteria.

As the skilled addressee would be aware, the bacteria can be exposed to the peptide by any means known in the art. In one embodiment, the bacteria is exposed to a composition comprising the peptide. In another embodiment, the bacteria is exposed to a host cell producing the peptide.

In a further aspect, the present invention provides a method of controlling bacterial infections of a crop, the method comprising cultivating a crop of transgenic plants of the invention.

In a further aspect, the present invention provides a method of treating or preventing a bacterial infection in a patient, the method comprising administering to the patient a peptide of the invention.

In addition, the present invention provides for the use of a peptide of the invention for the manufacture of a medicament for treating or preventing a bacterial infection in a patient.

It also has been discovered that the peptide of the invention is related to a family of molecules which had previously been shown to exhibit antibacterial activity (such as moricin from *Bombyx mori*), but had not been shown to have antifungal activity. However, the present inventors have discovered that the molecules related to those of the present invention also possess antifungal activity.

Thus, in a further aspect, the present invention provides a method for killing, or inhibiting the growth and/or reproduction of a fungus, the method comprising exposing the fungus to a peptide which comprises a sequence selected from the group consisting of:

i) an amino acid sequence comprising residues 25 to 67 of SEQ ID NO:14,

ii) an amino acid sequence comprising residues 26 to 67 of SEQ ID NO:15,

iii) an amino acid sequence comprising residues 25 to 66 of SEQ ID NO:16,

iv) an amino acid sequence as provided in SEQ ID NO:17,

v) an amino acid sequence comprising residues 26 to 66 of SEQ ID NO:18,

vi) an amino acid sequence which is at least 65% identical to any one of i) to v), and

vii) a biologically active fragment of any one of i) to vi).

In a preferred embodiment, the peptide is at least 70%, more preferably at least 80%, more preferably at least 85%, more preferably at least 90%, more preferably at least 92%, more preferably at least 95%, more preferably at least 97%, and even more preferably at least 99% identical to the sequence of any one of i) to vi).

Preferably, the peptide can be purified from an insect. More preferably, the peptide can be purified from a Lepidoptera. More preferably, the peptide can be purified from a Lepidoptera of a Family selected from the group consisting of Pyralidae, Noctuidae, Bombycidae, and Sphingidae.

In one embodiment, the peptide is provided as precursor such as SEQ ID NO: 14, SEQ ID NO:15, SEQ ID NO:16 or SEQ ID NO:18 which is processed to produce the biologically active peptide.

As the skilled addressee would be aware, the fungus can be exposed to the peptide by any means known in the art. In one embodiment, the fungus is exposed to a composition comprising the peptide. In another embodiment, the fungus is exposed to a host cell producing the peptide. In yet another embodiment, the fungus is exposed to a transgenic plant producing the peptide.

In a further aspect, the present invention provides a method of controlling fungal infections of a crop, the method comprising cultivating a crop of transgenic plants which produce a peptide which comprises a sequence selected from the group consisting of:

i) an amino acid sequence comprising residues 25 to 67 of SEQ ID NO:14,

ii) an amino acid sequence comprising residues 26 to 67 of SEQ ID NO:15,

iii) an amino acid sequence comprising residues 25 to 66 of SEQ ID NO:16,

iv) an amino acid sequence as provided in SEQ ID NO:17,

v) an amino acid sequence comprising residues 26 to 66 of SEQ ID NO:18,

vi) an amino acid sequence which is at least 65% identical to any one of i) to v), and

vii) a biologically active fragment of any one of i) to vi).

In a further aspect, the present invention provides a method of treating or preventing a fungal infection in a patient, the method comprising administering to the patient a peptide which comprises a sequence selected from the group consisting of:

i) an amino acid sequence comprising residues 25 to 67 of SEQ ID NO:14,

ii) an amino acid sequence comprising residues 26 to 67 of SEQ ID NO:15,
iii) an amino acid sequence comprising residues 25 to 66 of SEQ ID NO:16,
iv) an amino acid sequence as provided in SEQ ID NO:17,
v) an amino acid sequence comprising residues 26 to 66 of SEQ ID NO:18,
vi) an amino acid sequence which is at least 65% identical to any one of i) to v), and
vii) a biologically active fragment of any one of i) to vi).

In addition, the present invention provides for the use of a peptide which comprises a sequence selected from the group consisting of:

i) an amino acid sequence comprising residues 25 to 67 of SEQ ID NO:14,
ii) an amino acid sequence comprising residues 26 to 67 of SEQ ID NO:15,
iii) an amino acid sequence comprising residues 25 to 66 of SEQ ID NO:16,
iv) an amino acid sequence as provided in SEQ ID NO:17,
v) an amino acid sequence comprising residues 26 to 66 of SEQ ID NO:18,
vi) an amino acid sequence which is at least 65% identical to any one of i) to v), and
vii) a biologically active fragment of any one of i) to vi).

for the manufacture of a medicament for treating or preventing a fungal infection in a patient.

Also provided is a kit comprising a peptide, polynucleotide, vector, host cell, antibody or composition of the present invention.

In a further embodiment, the kit comprises other antimicrobial compounds such as those provided as SEQ ID NO's 14 to 18 or biologically active fragments thereof.

Preferably, the kit further comprises information and/or instructions for use of the kit.

As will be apparent, preferred features and characteristics of one aspect of the invention are applicable to many other aspects of the invention.

Throughout this specification the word "comprise", or variations such as "comprises" or "comprising", will be understood to imply the inclusion of a stated element, integer or step, or group of elements, integers or steps, but not the exclusion of any other element, integer or step, or group of elements, integers or steps.

The invention is hereinafter described by way of the following non-limiting Examples and with reference to the accompanying figures.

BRIEF DESCRIPTION OF THE ACCOMPANYING DRAWINGS

Figure 1. Sequence alignment of the nucleotide sequences of two Gm-moricinA cDNA clones (GmmoriAe - SEQ ID NO:6; GmmoriAc - SEQ ID NO:7). The sequence of GmmoriAe was the same as GmmoriAa and GmmoriAd, however, the latter two were

shorter at the 5' end. Non conserved nucleotides are underlined, with mutations resulting in amino acid substitutions in the putative Gm-moricinA precursor protein indicated by a double underline.

Figure 2. Sequence alignment of the deduced protein sequences of two Gm-moricinA cDNA clones (GmmoriAe - SEQ ID NO: 1; GmmoriAc - SEQ ID NO:2). Non conserved residues in clone GmmoriAc are underlined.

Figure 3. Nucleotide sequence and deduced pre-pro protein sequence of the *G. mellonella* Gm-moricinA cDNA clone pGmmoriAa (SEQ ID NO's 29 and 1 respectively). The deduced protein sequence commences at the first in-frame methionine residue. The presumptive secretion signal peptide is shown in italics and the mature Gm-moricinA peptide is highlighted in bold font. The peptide sequence obtained by Edman sequencing of the purified Gm-moricinA peptide is shown underlined. The predicted site of signal peptide cleavage (SignalP) is indicated below the peptide sequence by a single arrow and the predicted site of cleavage to generate the mature form of the peptide is indicated by a pair of arrows.

Figure 4. Nucleotide sequence and deduced pre-pro protein sequence of the *G. mellonella* Gm-moricinB cDNA (SEQ ID NO's 8 and 3 respectively). The deduced protein sequence commences at the first in-frame methionine residue. The presumptive secretion signal peptide is shown in italics and the mature Gm-moricinB peptide is highlighted in bold font. The peptide sequence obtained by Edman sequencing of the purified Gm-moricinB peptide is shown underlined. The predicted site of signal peptide cleavage (SignalP) is indicated below the peptide sequence by a single arrow and the predicted site of cleavage to generate the mature form of the peptide is indicated by a pair of arrows.

Figure 5. ClustalW alignment of the antifungal peptides from *G. mellonella* (GmmoriA - SEQ ID NO:1 and GmmoriB - SEQ ID NO:3) with related peptides from the lepidoptera *Bombyx mori* (Bmmor, P82818) (SEQ ID NO: 16), *Spodoptera litura* (Slmor, BAC79440) (SEQ ID NO: 14), *Manduca sexta* (Msmor, AAO74637) (SEQ ID NO: 15), *Heliothis virescens* (Hvvir, P83416) (SEQ ID NO: 17). Also included in the alignment is a previously unannotated putative moricin from *Bombyx mori* (BmmorX, translated open reading frame of BP125548) (SEQ ID NO: 18). The *G. mellonella* sequences correspond to the translated open reading frame from the cDNA sequences.

KEY TO THE SEQUENCE LISTING

SEQ ID NO:1 - Pre-Gm-moricinA from *Galleria mellonella.*

SEQ ID NO:2 - Allelic variant (GmmoriAc) of pre-Gm-moricinA from *Galleria mellonella.*

SEQ ID NO:3 - Pre-Gm-moricinB from *Galleria mellonella.*

SEQ ID NO:4 - Gm-moricinA from *Galleria mellonella.*

SEQ ID NO:5 - Gm-moricinB from *Galleria mellonella.*

SEQ ID NO:6 - cDNA encoding pre-Gm-moricinA including known 5' and 3' untranslated sequence from *Galleria mellonella.*

SEQ ID NO:7 - cDNA encoding allelic variant (GmmoriAc) of pre-Gm-moricinA including known 5' and 3' untranslated sequence from *Galleria mellonella.*

SEQ ID NO:8 - cDNA encoding pre-Gm-moricinB including known 5' and 3' untranslated sequence from *Galleria mellonella.*

SEQ ID NO:9 - cDNA encoding pre-Gm-moricinA from *Galleria mellonella.*

SEQ ID NO:10 - cDNA encoding allelic variant (GmmoriAc) of pre-Gm-moricinA from *Galleria mellonella.*

SEQ ID NO:11 - cDNA encoding pre-Gm-moricinB from *Galleria mellonella.*

SEQ ID NO:12 - cDNA encoding Gm-moricinA from *Galleria mellonella.*

SEQ ID NO:13 - cDNA encoding Gm-moricinB from *Galleria mellonella.*

SEQ ID NO:14 - Moricin-like peptide from *Spodoptera litura* (predicted mature peptide from Genbank Accession No. BAC79440).

SEQ ID NO:15 - Moricin-like peptide from *Manduca sexta* (predicted mature peptide from Genbank Accession No. AAO74637).

SEQ ID NO:16 - Moricin from *Bombyx mori* (Hara and Yamakawa (1995) and Genbank Accession No. P82818).

SEQ ID NO:17 - Virescein (moricin-like peptide) from *Heliothis virescens* (Genbank Accession No. P83416).

SEQ ID NO:18 - Putative *Bombyx mori* moricin (encoded by Genbank Accession BP125548).

SEQ ID NO:19 - N-terminal sequence of isolated Gm-moricinA.

SEQ ID NO:20 - N-terminal sequence of isolated Gm-moricinB.

SEQ ID NO's:21 to 28 - Oligonucleotide primers.

SEQ ID NO:29 - Polynucleotide sequence of clone GmmoriAa.

DETAILED DESCRIPTION OF THE INVENTION

General Techniques and Definitions

Unless specifically defined otherwise, all technical and scientific terms used herein shall be taken to have the same meaning as commonly understood by one of ordinary skill in the art (e.g., in cell culture, microbiology, molecular genetics, immunology, immunohistochemistry, protein chemistry, and biochemistry).

Unless otherwise indicated, the recombinant protein, cell culture, transgenic plant production and microbiological techniques utilized in the present invention are standard procedures, well known to those skilled in the art. Such techniques are described and explained throughout the literature in sources such as, J. Perbal, A Practical Guide to Molecular Cloning, John Wiley and Sons (1984), J. Sambrook et al., Molecular Cloning: A Laboratory Manual, Cold Spring Harbour Laboratory Press (1989), T.A. Brown (editor), Essential Molecular Biology: A Practical Approach, Volumes 1 and 2, IRL Press (1991), D.M. Glover and B.D. Hames (editors), DNA Cloning: A Practical Approach, Volumes 1-4, IRL Press (1995 and 1996), and F.M. Ausubel et al. (editors), Current Protocols in Molecular Biology, Greene Pub. Associates and Wiley-Interscience (1988, including all updates until present), and are incorporated herein by reference.

As used herein, the term "antifungal" peptide refers to a peptide having antifungal properties, e.g., which inhibits the growth of fungal cells, or which kills fungal cells, or which disrupts or retards stages of the fungal life cycle such as spore germination, sporulation, and mating.

As used herein, the term "antibacterial" peptide refers to a peptide having antibacterial properties, e.g., which inhibits the growth of bacterial cells, or which kills bacterial cells, or which disrupts or retards stages of the bacteria life cycle such as spore formation, and cell division.

Polypeptides/peptides

By "substantially purified peptide" we mean a peptide that has generally been separated from the lipids, nucleic acids, other peptides, and other contaminating molecules with which it is associated in its native state. Preferably, the substantially purified peptide is at least 60% free, more preferably at least 75% free, and more preferably at least 90% free from other components with which it is naturally associated.

The terms "polypeptide" and "peptide" are generally used interchangeably. However, the term "peptide" is typically used to refer to chains of amino acids which are not large, for instance 100 or less residues in length.

The % identity of a peptide is determined by GAP (Needleman and Wunsch, 1970) analysis (GCG program) with a gap creation penalty=5, and a gap extension penalty=0.3. The query sequence is at least 15 amino acids in length, and the GAP analysis aligns the two sequences over a region of at least 15 amino acids. More preferably, the query sequence is at least 50 amino acids in length, and the GAP analysis aligns the two sequences over a region of at least 50 amino acids. More preferably, the query sequence is at least 100 amino acids in length and the GAP analysis aligns the two sequences over a region of at least 100 amino acids. Even more preferably, the query sequence is at least 250 amino acids in length and the GAP analysis aligns the two sequences over a region of at least 250 amino acids.

As used herein a "biologically active" fragment is a portion of a peptide of the invention which maintains a defined activity of the full length peptide. In most embodiments this activity is antifungal activity, however, in some embodiments this activity is antibacterial. Biologically active fragments can be any size as long as they maintain the defined activity, however, in a preferred embodiment they are at least 10, more preferably at least 15, amino acids in length.

Amino acid sequence mutants of the peptides of the present invention, can be prepared by introducing appropriate nucleotide changes into a nucleic acid of the present invention, or by *in vitro* synthesis of the desired peptide. Such mutants include, for example, deletions, insertions or substitutions of residues within the amino acid sequence. A combination of deletion, insertion and substitution can be made to arrive at the final construct, provided that the final peptide product possesses the desired characteristics.

Mutant (altered) peptides can be prepared using any technique known in the art. For example, a polynucleotide of the invention can be subjected to *in vitro* mutagenesis. Such *in vitro* mutagenesis techniques include sub-cloning the polynucleotide into a suitable vector, transforming the vector into a "mutator" strain such as the *E. coli* XL-1 red (Stratagene) and propagating the transformed bacteria for a suitable number of generations. In another example, the polynucleotides of the invention are subjected to DNA shuffling techniques as broadly described by Harayama (1998). These DNA shuffling techniques may include genes related to those of the present invention, such as that encoding moricin from *B. mori* (Hara and Yamakawa, 1995). Peptide products derived from mutated/altered DNA can readily be screened using techniques described herein to determine if they possess antifungal and/or antibacterial activity.

In designing amino acid sequence mutants, the location of the mutation site and the nature of the mutation will depend on characteristic(s) to be modified. The sites for mutation can be modified individually or in series, e.g., by (1) substituting first with

conservative amino acid choices and then with more radical selections depending upon the results achieved, (2) deleting the target residue, or (3) inserting other residues adjacent to the located site.

Amino acid sequence deletions generally range from about 1 to 15 residues, more preferably about 1 to 10 residues and typically about 1 to 5 contiguous residues.

Substitution mutants have at least one amino acid residue in the peptide molecule removed and a different residue inserted in its place. The sites of greatest interest for substitutional mutagenesis include sites identified as the active site(s). Other sites of interest are those in which particular residues obtained from various strains or species are identical. These positions may be important for biological activity. These sites, especially those falling within a sequence of at least three other identically conserved sites, are preferably substituted in a relatively conservative manner. Such conservative substitutions are shown in Table 1 under the heading of "exemplary substitutions".

In particular, it has previously been shown that moricin possesses two α-helical structures (Hemmi *et al*, 2002). Considering the relatedness of the peptides of the invention to moricin-like peptides (see Figure 5), it is possible that a similar structure is also important for maintaining antifungal activity of the peptides of the invention. Accordingly, when designing mutants of, for example, SEQ ID NO:4 the skilled addressee, using knowledge of the chemistry of particular amino acids combined with known methods of predicting peptide tertiary structure, can readily produce peptides with one or a few amino acid variations when compared to SEQ ID NO:4 which possess antifungal activity.

Furthermore, if desired, unnatural amino acids or chemical amino acid analogues can be introduced as a substitution or addition into the peptides of the present invention. Such amino acids include, but are not limited to, the D-isomers of the common amino acids, 2,4-diaminobutyric acid, α-amino isobutyric acid, 4-aminobutyric acid, 2-aminobutyric acid, 6-amino hexanoic acid, 2-amino isobutyric acid, 3-amino propionic acid, ornithine, norleucine, norvaline, hydroxyproline, sarcosine, citrulline, homocitrulline, cysteic acid, t-butylglycine, t-butylalanine, phenylglycine, cyclohexylalanine, β-alanine, fluoro-amino acids, designer amino acids such as β-methyl amino acids, Cα-methyl amino acids, Nα-methyl amino acids, and amino acid analogues in general.

Table 1 - Exemplary substitutions

Original Residue	Exemplary Substitutions
Ala (A)	val; leu; ile; gly
Arg (R)	lys
Asn (N)	gln; his
Asp (D)	glu
Cys (C)	ser
Gln (Q)	asn; his
Glu (E)	asp
Gly (G)	pro, ala
His (H)	asn; gln
Ile (I)	leu; val; ala
Leu (L)	ile; val; met; ala; phe
Lys (K)	arg
Met (M)	leu; phe
Phe (F)	leu; val; ala
Pro (P)	gly
Ser (S)	thr
Thr (T)	ser
Trp (W)	tyr
Tyr (Y)	trp; phe
Val (V)	ile; leu; met; phe, ala

Also included within the scope of the invention are peptides of the present invention which are differentially modified during or after synthesis, e.g., by biotinylation, benzylation, glycosylation, acetylation, phosphorylation, amidation, derivatization by known protecting/blocking groups, proteolytic cleavage, linkage to an antibody molecule or other cellular ligand, etc. These modifications may serve to increase the stability and/or bioactivity of the peptide of the invention.

Peptides of the present invention can be produced in a variety of ways, including production and recovery of natural peptides, production and recovery of recombinant peptides, and chemical synthesis of the peptides. In one embodiment, an isolated peptide of the present invention is produced by culturing a cell capable of expressing the peptide under conditions effective to produce the peptide, and recovering the

peptide. A preferred cell to culture is a recombinant cell of the present invention. Effective culture conditions include, but are not limited to, effective media, bioreactor, temperature, pH and oxygen conditions that permit peptide production. An effective medium refers to any medium in which a cell is cultured to produce a peptide of the present invention. Such medium typically comprises an aqueous medium having assimilable carbon, nitrogen and phosphate sources, and appropriate salts, minerals, metals and other nutrients, such as vitamins. Cells of the present invention can be cultured in conventional fermentation bioreactors, shake flasks, test tubes, microtiter dishes, and petri plates. Culturing can be carried out at a temperature, pH and oxygen content appropriate for a recombinant cell. Such culturing conditions are within the expertise of one of ordinary skill in the art.

Polynucleotides

By "isolated polynucleotide" we mean a polynucleotide which has generally been separated from the polynucleotide sequences with which it is associated or linked in its native state. Preferably, the isolated polynucleotide is at least 60% free, more preferably at least 75% free, and more preferably at least 90% free from other components with which it is naturally associated. Furthermore, the term "polynucleotide" is used interchangeably herein with the term "nucleic acid molecule".

The % identity of a polynucleotide is determined by GAP (Needleman and Wunsch, 1970) analysis (GCG program) with a gap creation penalty=5, and a gap extension penalty=0.3. The query sequence is at least 45 nucleotides in length, and the GAP analysis aligns the two sequences over a region of at least 45 nucleotides. Preferably, the query sequence is at least 150 nucleotides in length, and the GAP analysis aligns the two sequences over a region of at least 150 nucleotides. Even more preferably, the query sequence is at least 300 nucleotides in length and the GAP analysis aligns the two sequences over a region of at least 300 nucleotides.

A polynucleotide of the present invention may selectively hybridise to a polynucleotide that encodes a peptide of the present invention under high stringency. Furthermore, oligonucleotides of the present invention have a sequence that hybridizes selectively under high stringency to a polynucleotide of the present invention. As used herein, high stringency conditions are those that (1) employ low ionic strength and high temperature for washing, for example, 0.015 M NaCl/0.0015 M sodium citrate/0.1% $NaDodSO_4$ at 50^0C; (2) employ during hybridisation a denaturing agent such as formamide, for example, 50% (vol/vol) formamide with 0.1% bovine serum albumin, 0.1% Ficoll, 0.1% polyvinylpyrrolidone, 50 mM sodium phosphate buffer at pH 6.5 with 750 mM NaCl, 75 mM sodium citrate at 42^0C; or (3) employ 50% formamide, 5 x SSC (0.75 M NaCl, 0.075 M sodium citrate), 50 mM sodium phosphate (pH 6.8),

0.1% sodium pyrophosphate, 5 x Denhardt's solution, sonicated salmon sperm DNA (50 g/ml), 0.1% SDS and 10% dextran sulfate at 42^{0}C in 0.2 x SSC and 0.1% SDS.

Polynucleotides of the present invention may possess, when compared to naturally occurring molecules, one or more mutations which are deletions, insertions, or substitutions of nucleotide residues. Mutants can be either naturally occurring (that is to say, isolated from a natural source) or synthetic (for example, by performing site-directed mutagenesis or DNA shuffling on the nucleic acid as described above). It is thus apparent that polynucleotides of the invention can be either naturally occurring or recombinant.

Oligonucleotides of the present invention can be RNA, DNA, or derivatives of either. The minimum size of such oligonucleotides is the size required for the formation of a stable hybrid between an oligonucleotide and a complementary sequence on a nucleic acid molecule of the present invention. The present invention includes oligonucleotides that can be used as, for example, probes to identify nucleic acid molecules, or primers to amplify nucleic acid molecules of the invention.

Recombinant Vectors

One embodiment of the present invention includes a recombinant vector, which comprises at least one isolated polynucleotide molecule of the present invention, inserted into any vector capable of delivering the polynucleotide molecule into a host cell. Such a vector contains heterologous polynucleotide sequences, that is polynucleotide sequences that are not naturally found adjacent to polynucleotide molecules of the present invention and that preferably are derived from a species other than the species from which the polynucleotide molecule(s) are derived. The vector can be either RNA or DNA, either prokaryotic or eukaryotic, and typically is a transposon (such as described in US 5,792,294), a virus or a plasmid.

One type of recombinant vector comprises a polynucleotide molecule of the present invention operatively linked to an expression vector. The phrase operatively linked refers to insertion of a polynucleotide molecule into an expression vector in a manner such that the molecule is able to be expressed when transformed into a host cell. As used herein, an expression vector is a DNA or RNA vector that is capable of transforming a host cell and of effecting expression of a specified polynucleotide molecule. Preferably, the expression vector is also capable of replicating within the host cell. Expression vectors can be either prokaryotic or eukaryotic, and are typically viruses or plasmids. Expression vectors of the present invention include any vectors that function (i.e., direct gene expression) in recombinant cells of the present invention, including in bacterial, fungal, endoparasite, arthropod, animal, and plant cells.

Particularly preferred expression vectors of the present invention can direct gene expression in plants cells.

In particular, expression vectors of the present invention contain regulatory sequences such as transcription control sequences, translation control sequences, origins of replication, and other regulatory sequences that are compatible with the recombinant cell and that control the expression of polynucleotide molecules of the present invention. In particular, recombinant molecules of the present invention include transcription control sequences. Transcription control sequences are sequences which control the initiation, elongation, and termination of transcription. Particularly important transcription control sequences are those which control transcription initiation, such as promoter, enhancer, operator and repressor sequences. Suitable transcription control sequences include any transcription control sequence that can function in at least one of the recombinant cells of the present invention. A variety of such transcription control sequences are known to those skilled in the art. Preferred transcription control sequences include those which function in bacterial, yeast, arthropod and mammalian cells, such as, but not limited to, tac, lac, trp, trc, oxy-pro, omp/lpp, rrnB, bacteriophage lambda, bacteriophage T7, T7lac, bacteriophage T3, bacteriophage SP6, bacteriophage SP01, metallothionein, alpha-mating factor, Pichia alcohol oxidase, alphavirus subgenomic promoters (such as Sindbis virus subgenomic promoters), antibiotic resistance gene, baculovirus, *Heliothis zea* insect virus, vaccinia virus, herpesvirus, raccoon poxvirus, other poxvirus, adenovirus, cytomegalovirus (such as intermediate early promoters), simian virus 40, retrovirus, actin, retroviral long terminal repeat, Rous sarcoma virus, heat shock, phosphate and nitrate transcription control sequences as well as other sequences capable of controlling gene expression in prokaryotic or eukaryotic cells. Particularly preferred transcription control sequences are promoters active in directing transcription in plants, either constitutively or stage and/or tissue specific, depending on the use of the plant or parts thereof. These plant promoters include, but are not limited to, promoters showing constitutive expression, such as the 35S promoter of Cauliflower Mosaic Virus (CaMV), those for leaf-specific expression, such as the promoter of the ribulose bisphosphate carboxylase small subunit gene, those for root-specific expression, such as the promoter from the glutamine synthase gene, those for seed-specific expression, such as the cruciferin A promoter from *Brassica napus*, those for tuber-specific expression, such as the class-I patatin promoter from potato or those for fruit-specific expression, such as the polygalacturonase (PG) promoter from tomato.

Recombinant molecules of the present invention may also (a) contain secretory signals (i.e., signal segment nucleic acid sequences) to enable an expressed peptide of the present invention to be secreted from the cell that produces the peptide and/or (b)

contain fusion sequences which lead to the expression of nucleic acid molecules of the present invention as fusion proteins. Examples of suitable signal segments include any signal segment capable of directing the secretion of a peptide of the present invention. Preferred signal segments include, but are not limited to, tissue plasminogen activator (t-PA), interferon, interleukin, growth hormone, viral envelope glycoprotein signal segments, *Nicotiana nectarin* signal peptide (US 5,939,288), tobacco extensin signal, the soy oleosin oil body binding protein signal, as well as native signal sequences of the peptide of the invention. In addition, a nucleic acid molecule of the present invention can be joined to a fusion segment that directs the encoded peptide to the proteosome, such as a ubiquitin fusion segment. Recombinant molecules may also include intervening and/or untranslated sequences surrounding and/or within the nucleic acid sequences of nucleic acid molecules of the present invention.

Host Cells

Another embodiment of the present invention includes a recombinant cell comprising a host cell transformed with one or more recombinant molecules of the present invention. Transformation of a polynucleotide molecule into a cell can be accomplished by any method by which a polynucleotide molecule can be inserted into the cell. Transformation techniques include, but are not limited to, transfection, electroporation, microinjection, lipofection, adsorption, and protoplast fusion. A recombinant cell may remain unicellular or may grow into a tissue, organ or a multicellular organism. Transformed polynucleotide molecules of the present invention can remain extrachromosomal or can integrate into one or more sites within a chromosome of the transformed (i.e., recombinant) cell in such a manner that their ability to be expressed is retained.

Although peptides discussed herein possess antifungal and antibacterial activity, suitable quantities of recombinant peptide of the invention can be obtained from bacterial or fungal host cells. More specifically, the peptide can be produced as a fusion protein, which is processed upon recovering the fusion protein from the recombinant host cell. An example of such a system is described by Hara and Yamakawa (1996) whereby moricin (SEQ ID NO:16) was produced as a fusion protein from *E. coli*. The fusion protein was harvested from the recombinant host cells and cleaved with cyanogen or o-iodosobenzoic acid to release the bioactive moricin peptide. A similar system could readily be devised to produce peptides of the present invention in bacterial or fungal host cells.

Suitable host cells to transform include any cell that can be transformed with a polynucleotide of the present invention. Host cells of the present invention either can be endogenously (i.e., naturally) capable of producing peptides of the present invention

or can be capable of producing such peptides after being transformed with at least one polynucleotide molecule of the present invention. Host cells of the present invention can be any cell capable of producing at least one protein of the present invention, and include bacterial, fungal (including yeast), parasite, arthropod, animal and plant cells. Examples of host cells include *Salmonella*, *Escherichia*, *Bacillus*, *Listeria*, *Saccharomyces*, *Spodoptera*, *Mycobacteria*, *Trichoplusia*, BHK (baby hamster kidney) cells, MDCK cells, CRFK cells, CV-1 cells, COS (e.g., COS-7) cells, and Vero cells. Further examples of host cells are *E. coli*, including *E. coli* K-12 derivatives; *Salmonella typhi*; *Salmonella typhimurium*, including attenuated strains; *Spodoptera frugiperda*; *Trichoplusia ni*; BHK cells; MDCK cells; CRFK cells; CV-1 cells; COS cells; Vero cells; and non-tumorigenic mouse myoblast G8 cells (e.g., ATCC CRL 1246). Additional appropriate mammalian cell hosts include other kidney cell lines, other fibroblast cell lines (e.g., human, murine or chicken embryo fibroblast cell lines), myeloma cell lines, Chinese hamster ovary cells, mouse NIH/3T3 cells, LMTK cells and/or HeLa cells. Particularly preferred host cells are plant cells such as those available from Deutsche Sammlung von Mikroorganismen und Zellkulturen GmbH (German Collection of Microorganisms and Cell Cultures).

Recombinant DNA technologies can be used to improve expression of a transformed polynucleotide molecule by manipulating, for example, the number of copies of the polynucleotide molecule within a host cell, the efficiency with which those polynucleotide molecules are transcribed, the efficiency with which the resultant transcripts are translated, and the efficiency of post-translational modifications. Recombinant techniques useful for increasing the expression of polynucleotide molecules of the present invention include, but are not limited to, operatively linking polynucleotide molecules to high-copy number plasmids, integration of the polynucleotide molecule into one or more host cell chromosomes, addition of vector stability sequences to plasmids, substitutions or modifications of transcription control signals (e.g., promoters, operators, enhancers), substitutions or modifications of translational control signals (e.g., ribosome binding sites, Shine-Dalgarno sequences), modification of polynucleotide molecules of the present invention to correspond to the codon usage of the host cell, and the deletion of sequences that destabilize transcripts.

Transgenic Plants

The term "plant" refers to whole plants, plant organs (e.g. leaves, stems roots, etc), seeds, plant cells and the like. Plants contemplated for use in the practice of the present invention include both monocotyledons and dicotyledons. Preferably, the transgenic plant is a commercially useful crop plant. Target crops include, but are not limited to, the following: cereals (wheat, barley, rye, oats, rice, sorghum and related

crops); beet (sugar beet and fodder beet); pomes, stone fruit and soft fruit (apples, pears, plums, peaches, almonds, cherries, strawberries, raspberries and black-berries); leguminous plants (beans, lentils, peas, soybeans); oil plants (rape, mustard, poppy, olives, sunflowers, coconut, castor oil plants, cocoa beans, groundnuts); cucumber plants (marrows, cucumbers, melons); fibre plants (cotton, flax, hemp, jute); citrus fruit (oranges, lemons, grapefruit, mandarins); vegetables (spinach, lettuce, asparagus, cabbages, carrots, onions, tomatoes, potatoes, paprika); lauraceae (avocados, cinnamon, camphor); or plants such as maize, tobacco, nuts, coffee, sugar cane, tea, vines, hops, turf, bananas and natural rubber plants, as well as ornamentals (flowers, shrubs, broad-leaved trees and evergreens, such as conifers). Particularly preferred crops include field peas, chickpeas, wheat and barley.

Transgenic plants, as defined in the context of the present invention include plants (as well as parts and cells of said plants) and their progeny which have been genetically modified using recombinant techniques to cause production of at least one peptide of the present invention in the desired plant or plant organ. Transgenic plants can be produced using techniques known in the art, such as those generally described in A. Slater et al., Plant Biotechnology - The Genetic Manipulation of Plants, Oxford University Press (2003), and P. Christou and H. Klee, Handbook of Plant Biotechnology, John Wiley and Sons (2004).

A polynucleotide of the present invention may be expressed constitutively in the transgenic plants during all stages of development. Depending on the use of the plant or plant organs, the peptides may be expressed in a stage-specific manner. Furthermore, depending on the use - particularly where the plant may be prone to fungal infection, the polynucleotides may be expressed tissue-specifically.

Regulatory sequences which are known or are found to cause expression of a gene encoding a peptide of interest in plants may be used in the present invention. The choice of the regulatory sequences used depends on the target plant and/or target organ of interest. Such regulatory sequences may be obtained from plants or plant viruses, or may be chemically synthesized. Such regulatory sequences are well known to those skilled in the art.

Other regulatory sequences such as terminator sequences and polyadenylation signals include any such sequence functioning as such in plants, the choice of which would be obvious to the skilled addressee. An example of such sequences is the 3' flanking region of the nopaline synthase (nos) gene of *Agrobacterium tumefaciens*.

Several techniques are available for the introduction of an expression construct containing a nucleic acid sequence encoding a peptide of interest into the target plants. Such techniques include but are not limited to transformation of protoplasts using the calcium/polyethylene glycol method, electroporation and microinjection or (coated)

particle bombardment. In addition to these so-called direct DNA transformation methods, transformation systems involving vectors are widely available, such as viral and bacterial vectors (e.g. from the genus *Agrobacterium*). After selection and/or screening, the protoplasts, cells or plant parts that have been transformed can be regenerated into whole plants, using methods known in the art. The choice of the transformation and/or regeneration techniques is not critical for this invention.

Examples of transgenic plants expressing antifungal peptides are described in Banzet et al. (2002) and EP 798381. In each case, the expression of the recombinant antifungal peptide resulted in the transgenic plant being resistant to fungal infections. Similar procedures as outlined in these documents can be used to produce peptides of the invention which confer resistance to fungal infections to the transgenic plant.

Transgenic Hon-Human Animals

Techniques for producing transgenic animals are well known in the art. A useful general textbook on this subject is Houdebine, Transgenic animals – Generation and Use (Harwood Academic, 1997).

Heterologous DNA can be introduced, for example, into fertilized mammalian ova. For instance, totipotent or pluripotent stem cells can be transformed by microinjection, calcium phosphate mediated precipitation, liposome fusion, retroviral infection or other means, the transformed cells are then introduced into the embryo, and the embryo then develops into a transgenic animal. In a highly preferred method, developing embryos are infected with a retrovirus containing the desired DNA, and transgenic animals produced from the infected embryo. In a most preferred method, however, the appropriate DNAs are coinjected into the pronucleus or cytoplasm of embryos, preferably at the single cell stage, and the embryos allowed to develop into mature transgenic animals.

Another method used to produce a transgenic animal involves microinjecting a nucleic acid into pro-nuclear stage eggs by standard methods. Injected eggs are then cultured before transfer into the oviducts of pseudopregnant recipients.

Transgenic animals may also be produced by nuclear transfer technology. Using this method, fibroblasts from donor animals are stably transfected with a plasmid incorporating the coding sequences for a binding domain or binding partner of interest under the control of regulatory sequences. Stable transfectants are then fused to enucleated oocytes, cultured and transferred into female recipients.

Compositions

Compositions of the present invention include "acceptable carriers". An acceptable carrier is preferably any material that the animal, plant, plant or animal

material, or environment (including soil and water samples) to be treated can tolerate. Examples of such acceptable carriers include water, saline, Ringer's solution, dextrose solution, Hank's solution, and other aqueous physiologically balanced salt solutions. Nonaqueous vehicles, such as fixed oils, sesame oil, ethyl oleate, or triglycerides may also be used.

Pharmaceutical compositions contain a therapeutically effective amount of an antifungal peptide of the invention. A therapeutically effective amount of an antifungal peptide can be readily determined according to methods known in the art. Pharmaceutical compositions are formulated to contain the therapeutically effective amount of an antifungal peptide and a pharmaceutically acceptable carrier appropriate for the route of administration (topical, gingival, intravenous, aerosol, local injection) as known to the art. For agricultural use, the composition comprises a therapeutically effective amount of a peptide of the invention and an agriculturally acceptable carrier suitable for the organism (e.g., plant) to be treated.

The phrase 'pharmaceutically acceptable carrier' refers to molecular entities and compositions that do not produce an allergic, toxic or otherwise adverse reaction when administered to an animal, particularly a mammal, and more particularly a human. Useful examples of pharmaceutically acceptable carriers or diluents include, but are not limited to, solvents, dispersion media, coatings, stabilizers, protective colloids, adhesives, thickeners, thixotropic agents, penetration agents, sequestering agents and isotonic and absorption delaying agents that do not affect the activity of the peptides of the invention. The proper fluidity can be maintained, for example, by the use of a coating, such as lecithin, by the maintenance of the required particle size in the case of dispersion and by the use of surfactants. More generally, the peptides of the invention can be combined with any non-toxic solid or liquid additive corresponding to the usual formulating techniques.

Liquid compositions of the invention include water-soluble concentrates, emulsifiable concentrates, emulsions, concentrated suspensions, aerosols, wettable powders (or powder for spraying), pastes and gels.

A peptide of the invention can also be used in the form of powders for dusting, and granules, in particular those obtained by extrusion, compacting, impregnation of a granular carrier or by granulation of a powder, and effervescent tablets or lozenges.

Surfactants may also form a component of various compositions. Surfactants can be an emulsifier, dispersant or wetting agent of ionic or nonionic type or a mixture of such surfactants. Examples include, but are not limited to, polyacrylic acid salts, lignosulfonic acid salts, phenolsulfonic or naphthalenesulfonic acid salts, polycondensates of ethylene oxide with fatty alcohols or with fatty acids or with fatty amines, substituted phenols (in particular alkyophenols or arylphenols), salts of

sulfosuccinic acid esters, taurine derivatives (in particular alkyl taurates), polyoxyethylated phosphoric esters of alcohols or of phenols, fatty acid esters of polyols, derivatives containing sulfate, sulfonate and phosphate functions of the above compounds.

Depending on the specific conditions being treated and the targeting method selected, such agents may be formulated and administered systemically or locally. Suitable routes may include, for example, oral, rectal, transdermal, vaginal, transmucosal, or intestinal administration; parenteral delivery, including intramuscular, subcutaneous, or intramedullary injections, as well as intrathecal, intravenous, or intraperitoneal injections.

For agricultural compositions, natural or synthetic, organic or inorganic materials may be used with which the compound is combined in order to facilitate its application to the plant, to seeds or the soil. This carrier is thus generally inert and it should be agriculturally acceptable, in particular on the plant treated. The carrier can be solid (clays, natural or synthetic silicates, silica, resins, waxes, solid fertilizers, etc.) or liquid (water, alcohols, in particular butanol, etc.).

Exposure of a plant pathogen to an antifungal peptide may be achieved by applying to plant parts or to the soil or other growth medium surrounding the roots of the plants or to the seed of the plant before it is sown using standard agricultural techniques such as spraying. The peptide may be applied to plants or to the plant growth medium in the form of a composition comprising the peptide in admixture with a solid or liquid diluent and optionally various adjuvants such as surface-active agents. Solid compositions may be in the form of dispersible powders, granules, or grains.

The compositions of the present invention can also be used in numerous products including, but not limited to, disinfectant hand soaps, hypo-allergenic hand care creme, shampoo, face soap, laundry products, dish washing products (including a bar glass dip) bathroom cleaning products, dental products (e.g., mouthwash, dental adhesive, saliva injector filters, water filtration) and deodorizing products.

One embodiment of the present invention is a controlled release formulation that is capable of slowly releasing a peptide of the present invention into an animal, plant, animal or plant material, or the environment (including soil and water samples). As used herein, a controlled release formulation comprises a peptide of the present invention in a controlled release vehicle. Suitable controlled release vehicles include, but are not limited to, biocompatible polymers, other polymeric matrices, capsules, microcapsules, microparticles, bolus preparations, osmotic pumps, diffusion devices, liposomes, lipospheres, and transdermal delivery systems. Preferred controlled release formulations are biodegradable (i.e., bioerodible).

The formulation is preferably released over a period of time ranging from about 1 to about 12 months. A preferred controlled release formulation of the present invention is capable of effecting a treatment preferably for at least about 1 month, more preferably for at least about 3 months, even more preferably for at least about 6 months, even more preferably for at least about 9 months, and even more preferably for at least about 12 months.

The effective concentration of the peptide, vector, or host cell within the composition can readily be determined experimentally, as will be understood by the skilled artisan.

Examples of compositions comprising antifungal peptides is provided in US 6,331,522. Similar compositions comprising the peptides of the invention could readily be produced by the skilled addressee.

Antibodies

The invention also provides monoclonal or polyclonal antibodies to peptides of the invention or fragments thereof. Thus, the present invention further provides a process for the production of monoclonal or polyclonal antibodies to peptides of the invention.

The term "binds specifically" refers to the ability of the antibody to bind to proteins of the present invention but not other known moricin-like peptides such as those provided in SEQ ID NO's 14 to 17.

As used herein, the term "epitope" refers to a region of a peptide of the invention which is bound by the antibody. An epitope can be administered to an animal to generate antibodies against the epitope, however, antibodies of the present invention preferably specifically bind the epitope region in the context of the entire peptide.

If polyclonal antibodies are desired, a selected mammal (e.g., mouse, rabbit, goat, horse, etc.) is immunised with an immunogenic peptide. Serum from the immunised animal is collected and treated according to known procedures. If serum containing polyclonal antibodies contains antibodies to other antigens, the polyclonal antibodies can be purified by immunoaffinity chromatography. Techniques for producing and processing polyclonal antisera are known in the art. In order that such antibodies may be made, the invention also provides peptides of the invention or fragments thereof haptenised to another peptide for use as immunogens in animals.

Monoclonal antibodies directed against peptides of the invention can also be readily produced by one skilled in the art. The general methodology for making monoclonal antibodies by hybridomas is well known. Immortal antibody-producing cell lines can be created by cell fusion, and also by other techniques such as direct transformation of B lymphocytes with oncogenic DNA, or transfection with Epstein-

Barr virus. Panels of monoclonal antibodies produced can be screened for various properties; i.e., for isotype and epitope affinity.

An alternative technique involves screening phage display libraries where, for example the phage express scFv fragments on the surface of their coat with a large variety of complementarity determining regions (CDRs). This technique is well known in the art.

For the purposes of this invention, the term "antibody", unless specified to the contrary, includes fragments of whole antibodies which retain their binding activity for a target antigen. Such fragments include Fv, F(ab') and $F(ab')_2$ fragments, as well as single chain antibodies (scFv). Furthermore, the antibodies and fragments thereof may be humanised antibodies, for example as described in EP-A-239400.

Antibodies of the invention may be bound to a solid support and/or packaged into kits in a suitable container along with suitable reagents, controls, instructions and the like.

Preferably, antibodies of the present invention are detectably labeled. Exemplary detectable labels that allow for direct measurement of antibody binding include radiolabels, fluorophores, dyes, magnetic beads, chemiluminescers, colloidal particles, and the like. Examples of labels which permit indirect measurement of binding include enzymes where the substrate may provide for a coloured or fluorescent product. Additional exemplary detectable labels include covalently bound enzymes capable of providing a detectable product signal after addition of suitable substrate. Examples of suitable enzymes for use in conjugates include horseradish peroxidase, alkaline phosphatase, malate dehydrogenase and the like. Where not commercially available, such antibody-enzyme conjugates are readily produced by techniques known to those skilled in the art. Further exemplary detectable labels include biotin, which binds with high affinity to avidin or streptavidin; fluorochromes (e.g., phycobiliproteins, phycoerythrin and allophycocyanins; fluorescein and Texas red), which can be used with a fluorescence activated cell sorter; haptens; and the like. Preferably, the detectable label allows for direct measurement in a plate luminometer, e.g., biotin. Such labeled antibodies can be used in techniques known in the art to detect peptides of the invention.

Uses

The peptides of the invention have many uses in medical, veterinary, agricultural, food preservative, household and industrial areas where it is desirable to reduce and/or prevent fungal or bacterial infections.

For instance, the peptides of the present invention can be used in pharmaceutical compositions to treat fungal infections, as well as bacterial infections (e.g., *S. mutans*, *P*

aeruginosa or *P. gingivalis* infections). Vaginal, urethral, mucosal, respiratory, skin, ear, oral, or ophthalmic fungal or bacterial infections that are amenable to peptide therapy include, but are not limited to: *Candida albicans; Actinomyces actinomycetemcomitans; Actinomyces viscosus; Bacteriodesforsythus; Bacteriodesfragilis; Bacteriodes gracilis; Bacteriodes ureolyticus; Campylobacter concisus; Campylobacter rectus; Campylobacter showae; Campylobacter sputorum; Capnocytophaga gingivalis; Capnocytophaga ochracea; Capnocytophaga sputigena; Clostridium histolyticum; Eikenella corrodens; Eubacterium nodatum; Fusobacterium nucleatum; Fusobacterium periodonticum; Peptostreptococcus micros; Porphyromonas endodontalis; Porphyromonas gingivalis; Prevotella intermedia; Prevotella nigrescens; Propionibacterium acnes; Pseudomonas aeruginosa; Selenomonas noxia; Staphylococcus aureus; Streptococcus constellatus; Streptococcus gordonii; Streptococcus intermedius; Streptococcus mutans; Streptococcus oralis; Streptococcus pneumonia; Streptococcus sanguis; Treponema denticola; Treponema pectinovorum; Treponema socranskii; Veillonellaparvula;* and *Wolinella succinogenes.*

For agricultural applications, the antifungal peptide may be used to improve the disease-resistance or disease-tolerance of crops either during the life of the plant or for post-harvest crop protection. The growth of pathogens exposed to the peptides is inhibited. The antifungal peptide may eradicate a pathogen already established on the plant or may protect the plant from future pathogen attack. A pathogen may be any fungus growing on, in or near the plant. Improved resistance is defined as enhanced tolerance of the plant, or the crop after harvesting, to a fungal pathogen when compared to a wild-type plant. Resistance may vary from a slight decrease in the effects, to the total eradication so that the plant is unaffected by the presence of pathogen.

Thus, peptides of the invention can also be used to treat and/or prevent fungal infections of plants. Such plant fungi include, but are not limited to, those selected from the group consisting of the Genera: Alternaria; Ascochyta; Botrytis; Cercospora; Colletotrichum; Diplodia; Erysiphe; Fusarium; Leptosphaeria; Gaeumanomyces; Helminthosporium; Macrophomina; Nectria; Peronospora; Phoma; Phymatotrichum; Phytophthora; Plasmopara; Podosphaera; Puccinia; Puthium; Pyrenophora; Pyricularia; Pythium; Rhizoctonia; Scerotium; Sclerotinia; Septoria; Thielaviopsis; Uncinula; Venturia; and Verticillium. Specific examples of plant fungi infections which can be treated with the peptides of the present invention include, *Erysiphe graminis* in cereals, *Erysiphe cichoracearum* and *Sphaerotheca fuliginea* in cucurbits, *Podosphaera leucotricha* in apples, *Uncinula necator* in vines, *Puccinia sp.* in cereals, *Rhizoctonia sp.* in cotton, potatoes, rice and lawns, *Ustilago sp.* in cereals and sugarcane, *Venturia inaequalis* (scab) in apples, *Helminthosporium sp.* in cereals, *Septoria nodorum* in wheat, *Septoria tritici* in wheat, *Rhynchosporium secalis* on barley, *Botrytis cinerea*

(gray mold) in strawberries, tomatoes and grapes, *Cercospora arachidicola* in groundnuts, *Peronospora tabacina* in tobacco, or other *Peronospora* in various crops, *Pseudocercosporella herpotrichoides* in wheat and barley, *Pyrenophera teres* in barley, *Pyricularia oryzae* in rice, *Phytophthora infestans* in potatoes and tomatoes, *Fusarium sp.* and *Verticillium sp.* in various plants, *Plasmopara viticola* in grapes, *Alternaria sp.* in fruit and vegetables, *Pseudoperonospora cubensis* in cucumbers, *Mycosphaerella fijiensis* in banana, *Ascochyta sp.* in chickpeas, *Leptosphaeria sp.* on canola, and *Colleotrichum sp.* in various crops.

An antifungal peptide according to the invention may also be used as a preservative to maintain the freshness and shelf life of food products such as cheese, bread, cakes, meat, fish, preserves, feed for animals and the like. The antifungal peptide may also be used in antimicrobial food packaging such as coating plastics or polymers or incorporation within edible coating or films. For example peptide coatings and films can contain adequate amounts of antifungal peptide(s) for use on such products as cheese, sweets, dried goods and the like.

EXAMPLES

Example 1 - Peptide Purification

Materials and Methods

Insects

Galleria mellonella (wax moth) were reared on an artificial diet. Last instar larvae were injected with 10 µl of water containing approximately 10^6 cells of each of *Escherichia coli* and *Micrococcus luteus*. As a control, some larvae were injected with 10 µl of phosphate buffered saline solution. Larvae were left at room temperature for 48 hours before extracting hemolymph by removal of a proleg. Hemolymph was collected on ice in a tube containing a few crystals of phenylthiourea, centrifuged for 5 min to remove cell debris, and frozen at -80 °C.

Antifungal and antibacterial activity assays

Samples were tested for activity using an inhibition zone plate assay. For the bacteria *Escherichia coli* and *Micrococcus luteus*, plates were prepared using nutrient agar (Oxoid) and a cell density of approximately 5 x 10^6 cells/ml.

For fungi, plates were prepared using YPD broth (10g/l yeast extract, 10g/l peptone, 40g/l *D*-glucose) containing 0.8% agarose and a spore density of approximately 10^6 spores/ml. To test for activity, 2 µl of the sample of interest was spotted on the surface of the plate, and the organism grown under appropriate conditions (overnight at 37 °C for bacteria, 1-3 days at room temperature for fungi) until the presence or absence of clearance zones could be detected. The fungi tested

were *Fusarium graminearum*, *Alternaria alternata*, *Ascochyta rabiei*, *Colletotrichum gloeosporioides*, *Leptosphaeria maculans* and *Aspergillus niger*.

Peptide purification

Approximately 1.4 ml of thawed *G. mellonella* hemolymph was diluted into an equal volume of 0.1% trifluoroacetic acid (TFA), and shaken on ice for 30 min. This sample was centrifuged at high speed for 10 min, the supernatant removed and precipitated with 20% acetonitrile/0.05% TFA, and re-centrifuged for 5 min at high speed. The supernatant was loaded onto three C18 solid phase extraction cartridges (Maxi-Clean, 300 mg cartridges, Alltech) each of which had been equilibrated in 20% acetonitrile/0.05% TFA. The three cartridges were washed with 20% acetonitrile/0.05% TFA, before elution with 60% acetonitrile/0.05% TFA. The three eluted samples were dried in a Speedvac (Savant) and each sample resuspended in 100 µl water. The pooled samples were tested against *E. coli*, *M. luteus* and all six fungi using the plate assay described above.

The crude hemolymph sample was purified by reverse phase HPLC on a Beckman Gold system monitoring absorbance at 225 or 215 nm. The sample was loaded onto a Jupiter C18, 5 µm, 300 Å, 250 x 10mm semi-prep column (Phenomenex) equilibrated in solvent A (2% acetonitrile, 0.065% TFA), and eluted with a gradient from 0-70% solvent B (95% acetonitrile, 0.05% TFA) over 70 min at 5 ml/min. 500 µl of each 5 ml fraction was dried in the Speedvac, resuspended in 10 µl water, and tested for activity against *E. coli*, *M. luteus* and *F. graminearum*, as described above.

For Gm-moricinA, the fraction of interest was diluted in an equal volume of 0.05% TFA and loaded onto a Prosphere C18, 5 µm, 300 Å, 250 x 4.6mm analytical column (Alltech) equilibrated in 10% solvent B on the HPLC. The column was eluted with a gradient of 10-50% B running over 60 min at 1ml/min. 200 µl of each 1.8 ml fraction was dried in the Speedvac, resuspended in 10 µl water and tested for activity against *E. coli*, *M. luteus* and *F. graminearum*. The fraction of interest was diluted in an equal volume of 0.05% TFA and loaded onto a Macrosphere C8, 5 µm, 300 Å, 250 x 4.6mm analytical column (Alltech) equilibrated in 15% solvent B on the HPLC. The column was eluted with a gradient of 15-55% solvent B running over 60 min at 1ml/min. 300 µl of each 1.8 ml fraction was dried in the Speedvac, resuspended in 10 µl water and tested for activity against *E. coli*, *M. luteus* and *F. graminearum*.

For Gm-moricinB, the fraction of interest was diluted in an equal volume of 0.05% TFA and loaded onto a Prosphere C18, 5 µm, 300 Å, 250 x 4.6mm analytical column (Alltech) equilibrated in 15% solvent B on the HPLC. The column was eluted with a gradient of 15-65% B running over 75 min at 1ml/min. 200 µl of each 1.8 ml fraction was dried in the Speedvac, resuspended in 10 µl water and tested for activity

against *E. coli*, *M. luteus* and *F. graminearum*. The fraction of interest was diluted in an equal volume of 0.05% TFA and loaded onto a Macrosphere C8, 5 µm, 300 Å, 250 x 4.6mm analytical column (Alltech) equilibrated in 15% solvent B on the HPLC. The column was eluted with a gradient of 15-55% solvent B running over 60 min at 1ml/min. 200 µl of each 1.8 ml fraction was dried in the Speedvac, resuspended in 10 µl water and tested for activity against *E. coli*, *M. luteus* and *F. graminearum*. The fraction of interest was diluted in an equal volume of 0.05% TFA and loaded onto a µRPC C2/C18, 3 µm, 100 x 2.1mm analytical column (Amersham Biosciences) equilibrated in solvent A running on a SMART system (Amersham Biosciences) monitoring at 215, 254 and 280 nm. The column was eluted with a gradient of 0-100% solvent B running over 25 min at 200 µl/min. 50 µl of each 1.8 ml fraction was dried in the Speedvac, resuspended in 3 µl water and tested for activity against *F. graminearum*.

Peptide identification

The fractions of interest were analysed on a Voyager Elite MALDI-TOF mass spectrometer (Perseptive Biosystems) using 0.5 µl of sample plus 0.5µl of matrix. For linear mode spectra the matrix was sinapinic acid and the standard was a mixture of cecropin A and myoglobin, and for reflector mode spectra the matrix was α-cyano-4-hydroxycinnamic acid and the standard was a tryptic digest of bovine serum albumin. For N-terminal amino acid sequencing the purified peptides were dried onto fibre glass disks and subject to Edman degradation using a Procise Model 492 Protein Sequencer (Applied Biosystems), in accordance with the manufacturers instructions.

Results and Discussion

The crude hemolymph sample obtained after partial purification by C18 solid phase extraction showed activity against *E. coli*, *M. luteus* and all six fungi. Further purification of this sample on a C18 semi-prep column produced seven fractions that eluted between approximately 25-40% acetonitrile that showed activity against the test organism *F. graminearum*. Two of these fractions – one from earlier and one from later in the gradient – were purified further on a C18 analytical column. For Gm-moricinA, three fractions were obtained which had activity against *F. graminearum*. One of these fractions was purified further on a C8 analytical column, producing one fraction which had activity against *F. graminearum*. It also showed activity against *L. maculans* and *A. rabiei*, but had no detectable activity against the bacteria *E. coli* and *M. luteus*. This fraction appeared sufficiently pure as judged by mass spectroscopy, that it was subjected to Edman sequencing without further purification. For Gm-moricinB, purification on the C18 analytical column resulted in one fraction that

showed activity against *F. graminearum*, so this fraction was purified further on a C8 analytical column, resulting in one fraction which had activity against *F. graminearum*. This fraction was further purified on a C2/C18 column, resulting in one fraction which showed activity against *F. graminearum*. This fraction appeared sufficiently pure by mass spectroscopy and was sequenced by Edman degradation.

MALDI mass spectroscopy and Edman sequencing were used to identify the purified peptides. Gm-moricinA had an apparent molecular weight of 4245 and a partial amino acid sequence of KVNVNAIKKGGKAIGKGFKVISAASTAHDVYE (SEQ ID NO:19). For Gm-moricinB, the mass spectrum consisted of one major peak (3566) plus several minor components, so it was not possible to be certain of the molecular weight of the active component. The amino acid sequence of the main component was determined to be GGQIIGKALRGINIASTAHDIISQFKPK (SEQ ID NO:20). Searches of the non-redundant databases using BLASTP for short matches indicated that these two peptides had some homology to the known peptides moricin from *Bombyx mori*, *Manduca sexta* and *Spodoptera litura*, and virescein from *Heliothis virescens*.

Example 2 - Identification of cDNAs Encoding *G. mellonella* Moricin-Like Peptides

Preparation of total RNA and poly(A)$^+$ RNA

Fat body tissue was dissected from *G. mellonella* larvae at 24 hours after injection with *E. coli* and *M. luteus* cell suspension. Larvae that had been chilled on ice for at least 30 min were pinned in a Sylgard dish under ice-cold PBS and opened by a longitudinal incision down the dorsal midline. The gut was removed and fat body was collected with fine watch-makers forceps. Dissected fat body was briefly blotted on absorbent tissue and snap-frozen in a microfuge tube held in liquid nitrogen. The frozen tissues were stored at -80°C.

Total RNA was isolated using Trizol reagent (Astral Scientific). Briefly, approximately 500 mg of frozen fat body tissue was resuspended in 1mL of Trizol reagent and homogenised in a Polytron tissue homogeniser.

Polyadenylated RNA was isolated by two rounds of selection on oligo(dT)-cellulose spun-column chromatography using the mRNA purification kit (Amersham Biosciences). Approximately 1 mg of total RNA was bound to an oligo(dT)-cellulose spin column, washed and eluted in 1 mL of low salt buffer according to the manufacturer's instructions. The eluted RNA was bound to a second spin column, washed and eluted as described above in a final volume of 1 mL. The mRNA was precipitated by addition of sodium acetate to a final concentration of 0.1M with 200 µL

ethanol. The mRNA was recovered by centrifugation and resuspended in 5 µL of DEPC-treated water.

Preparation of a cDNA library

A cDNA library was prepared from approximately 5 µg of mRNA using a Lambda UniZap cDNA synthesis and cloning system (Stratagene). Purified cDNA (approx. 20 ng) was ligated to 1µg of vector DNA and packaged with Gigapack® III Gold packaging extract (Stratagene) to yield a cDNA library with a titre of 5 x 10^5 plaque forming units per mL.

Identification of cDNA encoding moricin-like peptides by PCR

Short, minimally degenerate oligonucleotides were designed by reverse translation of the amino-acid sequences of each of the *G. mellonella* moricin-like peptides. The sequences of these oligonucleotides are given in the Table 2.

Table 2 Primers used for identification of *G. mellonella* moricin cDNAs

Peptide	Primer name	Orientation	Sequence†
Gm-moricinA	GmAF1	sense strand	5'-AAYGTIAAYGCIATHAARAARGG-3' (SEQ ID NO: 21)
Gm-moricinA	GmAF2	antisense strand	5'-YTCRTAIACRGCRTGIGCNTG-3' (SEQ ID NO: 22)
Gm-moricinB	GmAF3	sense strand	5'-GGIGGICARATHATHGGIAARGC-3' (SEQ ID NO: 23)
Gm-moricinB	GmAF4	antisense strand	5'-TGISIDATDATRTCRTGIGCNGT-3' (SEQ ID NO: 24)

† deoxy-inosine triphosphate (I) was used in some positions to reduce overall degeneracy of the oligonucleotide pool.

Each of the oligonucleotide pairs GmAF1/GmAF2 and GmAF3/GmAF4 were used as primers for polymerase chain reaction amplification of fragments of cDNA encoding the Gm-moricinA and Gm-moricinB peptides. Approximately 2ng of the purified double-stranded cDNA used for library construction was used as template for the PCR reactions.

PCR products of the expected size were excised from acrylamide gels and the DNA was eluted in ammonium acetate buffer and recovered by ethanol precipitation. The purified DNA was ligated into the cloning vector pGEM-Teasy (Promega) and transformed by electroporation into *E. coli* DH10B cells. Resultant bacterial colonies were screened for inserts by PCR using primers based on the T7 and SP6 promoter sequences flanking the multiple cloning site of the vector. For each of the Gm-moricinA and Gm-moricinB PCR products, several clones containing inserts of the

expected size were sequenced on both strands and the deduced protein sequence was used to verify the clones as true Gm-moricinA and Gm-moricinB cDNA products. A representative clone was selected for each moricin cDNA type for subsequent use in library screening.

Probe synthesis

Probes were synthesised in PCR reactions in which the dATP was replaced by radio-labelled dATP. Unique sequence primers were designed from a representative clone for each of the Gm-moricinA and Gm-moricinB cDNA fragments (Table 3). Hybridisation probes were prepared for each of the *G. mellonella* moricin cDNAs using the primers described in Table 3 and the cDNA inserts of clones pGmmA7 (Gm-moricinA) and pGmmB11 (Gm-moricinB) as template.

Table 3. Partial clones and oligonucleotide primers used for preparation of hybridisation probes for library screening

Clone	Primer name	Orientation	Sequence
pGmmA7	GmLM1	sense strand	5'- GAGGAAAGGCCATAGGAAAAGG -3' (SEQ ID NO: 25)
pGmmA7	GmLM2	antisense strand	5'- ACTCGCCGCACTGATTAC -3' (SEQ ID NO: 26)
pGmmB11	GmSM1	sense strand	5'- GGGGGGCAGATCATTGGG -3' (SEQ ID NO: 27)
pGmmB11	GmSM2	antisense strand	5'- TTATGTCATGGGCCGTACT -3' (SEQ ID NO: 28)

The compositions of the PCR reactions for each of the two probes are described in Table 4. Reaction conditions consisted of an initial denaturing step of 94°C for 3 min, followed by 30 cycles of 94°C for 45 sec, 53°C for 30 sec, 72°C for 45 sec, and a final step of 72°C for 5 min to end.

Unincorporated dNTPs were removed from the completed reactions using size exclusion spun column chromatography (BioRad P30 micro bio-spin columns) and incorporation of radioisotope was monitored by TLC.

Library screening

The cDNA library was plated onto five 15cm LB agar plates at a density of 5 x 10^4 pfu per plate. Duplicate plaque lifts were made on nitrocellulose filters, and the DNA was denatured and fixed to the membranes using standard procedures (Sambrook et al., 1989, supra).

The library was screened first with the probe for the *G. mellonella* Gm-moricinA gene and the primary filters were washed and re-screened with the probe for the *G. mellonella* Gm-moricinB gene.

Table 4. Probe labelling reaction conditions

Reagent	Gm-moricinA Probe	Gm-moricinB Probe
10x PCR buffer	5µl	5µl
50mM $MgCl_2$	1.5µl	1.5µl
10mm dNTPs (mix of dCTP, dGTP, dTTP)	1µl	1µl
10µM sense strand primer	3µl GmLM1	6µl GmSM1
10µM anti-sense strand primer	3µl GmLM2	6µl GmSM2
ddH_2O	35µl	30µl
Template	1µl pGmmA7 insert (1 in 10 dilution)	1µl pGmmB11 insert (1 in 10 dilution)
α-(^{32}P)-dATP	5µl	5µl
Taq Polymerase (5U/µl)	0.5µl	0.5µl

Filters were placed in hybridisation bottles (Hybaid) and prehybridised for a minimum of 2 hours at 60°C in 20 ml of a solution containing 5XSSPE, 5X Denhardt's solution, 0.5% w/v SDS, and 200µg/ml freshly denatured herring sperm DNA. The probe was denatured by boiling for 10 min followed by chilling on ice. The cooled probe solution was added to the filters and allowed to hybridise overnight at 60°C.

Filters were washed three times in 0.5X SSPE, 0.1% SDS at 60°C for 30 minutes per change.

Isolation and characterisation of cDNA encoding the G. mellonella *Gm-moricinA peptide*

Approximately 80 hybridising phages were identified from the primary library screen. Four of these were plaque-purified, the plasmids excised, and the cDNA inserts sequenced on both strands by dye-terminator sequencing using a Beckman CEQ8000 DNA Analyser and Beckman DCTS chemistry. Three clones were identified (pGmmoriAa, pGmmoriAd, pGmmoriAe) that differed only in length at the 5'-end. The fourth clone (pGmmoriAc) was an allelic variant of the same gene that differed

from the other three by 6 nucleotide substitutions, two of which resulted in amino acid replacements in the presumptive secretion signal peptide. The other changes were either silent or occurred in untranslated regions of the mRNA. The nucleotide sequences of two of these Gm-moricinA cDNA clones are shown as a sequence alignment in Figure 1, and the deduced amino acid sequences are presented as a sequence alignment in Figure 2.

The nucleotide sequence of clone pGmmoriAa, representing the most common clone class, is shown in Figure 3, together with the deduced protein sequence of the open reading frame encoding the Gm-moricinA peptide, commencing at the first in-frame methionine residue. Sites of predicted protein precursor processing are also indicated on the figure.

Isolation and characterisation of cDNA encoding the G. mellonella *Gm-moricinB peptide*

In excess of 150 hybridising phages were identified from the primary library screen. Three clones were plaque-purified, the plasmids excised, and the cDNA inserts sequenced on both strands by dye-terminator sequencing using a Beckman CEQ8000 DNA Analyser and Beckman DCTS chemistry. These clones, designated pGmmoriBe1, pGmmoriBe2 and pGmmoriBd1, differed only in length at the 5'-end.

The nucleotide sequence of a representative clone, pGmmoriBe1, is shown in Figure 4, together with the deduced protein sequence of the open reading frame encoding the *G. mellonella* Gm-moricinB peptide, commencing at the first in-frame methionine residue.

Discussion

For both Gm-moricinA and Gm-moricinB, the partial sequences determined by N-terminal amino acid sequencing were identical to sections of the translated cDNA sequences. This allowed extraction of the complete sequences of the two peptides from the predicted open reading frames of the corresponding cDNA sequences. The deduced sequences of the mature peptides were used to search the non-redundant databases using BLASTP for short matches. These searches indicated that Gm-moricinA had homology to moricin from *Bombyx mori* (48% identity), *Manduca sexta* (56% identity) and *Spodoptera litura* (67% identity), and virescein from *Heliothis virescens* (64% identity). Similarly, Gm-moricinB showed homology to moricin from *Bombyx mori* (63% identity), *Manduca sexta* (70% identity) and *Spodoptera litura* (76% identity), and virescein from *Heliothis virescens* (69% identity). The ClustalW alignment of Gm-moricinA and Gm-moricinB with the related peptides from other lepidoptera is shown in Figure 5. By combining information from this alignment, the amino acid

sequencing, and knowledge about signal peptide processing of insect antimicrobial peptides (Boman et al., 1989), the mature peptides are most likely to start at residue 25 (*B. mori* and *S. litura* moricin) or residue 26 (*G. mellonella* Gm-moricinA, *M. sexta* moricin and *B. mori* moricinX) (Figure 5). Thus, for Gm-moricinA, the mature peptide has a calculated molecular weight of 4244, which is close to the major peak of 4245 Da that was observed in the mass spectrum. For Gm-moricinB, the situation is more complex because the N-terminal amino acid sequencing suggests that the active peptide starts at residue 36. The molecular weight of Gm-moricinB starting at position 36 is 3570, which corresponds to the major peak of 3566 Da that was observed in the mass spectrum. The previously known moricin-like peptides from lepidoptera are only reported to have antibacterial activity. This indicates that both Gm-moricinA and Gm-moricinB have novel antifungal activities.

Example 3 - Molecules related to Gm-moricinA or Gm-moricinB possess antifungal activity

B. mori moricin (residues 25 to 66 of SEQ ID NO:16) was synthesized by Auspep (Parkville, Australia) using standard peptide synthesis techniques. The peptide was tested against *E. coli*, *M. luteus* and *F. graminearum* generally as described in Example 1. The peptide had activity against each organism at a concentration between 1 and 10μM, most importantly antifungal activity against *F. graminearum*.

Example 4 - Expression of antifungal peptides in *Arabidopsis*

Agrobacterium-*mediated transformation of* Arabidopsis *with antifungal genes*

cDNA encoding Gm- moricinA or Gm-moricinB is cloned into an *Agrobacterium* transfer vector, pART27, which contains flanking regions of homologous *Agrobacterium* DNA. Transformation of the *Agrobacterium* strain GV3101 can be achieved using the triparental mating method or standard electroporation.

Briefly, triparental mating involves co-streaking cultures of A. tumefasciens GV3101, E.coli carrying a helper plasmid, RK2013, and E.coli carrying the desired recombinant pART27 plasmid onto a non-selective LB plate. Overnight incubation at 28oC results in a mixed culture which is collected and dilution streaked onto LB plates which select for A. tumefasciens GV3101 carrying the pART27 recombinant plasmid.

Transformation of *Arabidopsis* plants is carried out by floral dipping. Plants are grown to an age, 3-5 weeks, where there are many flower stems presenting flowers at various stages of development. An overnight culture of transformed A. tumefasciens GV3101 is pelleted and resuspended in 5% sucrose containing the wetting agent Silwet-77. Flowers are dipped into the bacterial suspension and thoroughly wetted by

using a sweeping motion. The plants are wrapped in plastic film and left overnight on a bench top at room temperature, before being unwrapped and placed back into a plant growth cabinet maintained at 21°C. The dipping is repeated 1-2 weeks later to increase the number of transformed seeds. The seeds are collected 3-4 weeks after dipping. They are dried in seed envelopes for the appropriate length of time for each ecotype, then sterilised and germinated on Noble agar plates containing selective antibiotics and an antifungal agent.

Positive transformants are transplanted into arasystem pots, grown to maturity inside aracon system sleeves and the seeds carefully collected. The transformed *Arabidopsis* plants are screened by PCR to confirm the presence and genetic location of the recombinant gene.

Inoculation protocol using Fusarium oxysporum

The fungal isolate is maintained on carnation leaf agar and ½ strength Potato Dextrose Agar (PDA).

From maintenance stocks, cores are taken and used to inoculate 50ml Potato Dextrose Broth (PDB). Flasks are incubated on a shaker for 2–3 days. Inoculum is drained through miracloth prior to quantification with a haemocytometer. Spores are diluted with sterile distilled water and used to inoculate *Arabidopsis* strains.

Arabidopsis plants used in the inoculation are grown in 'jiffy' pots for approximately 2-3 weeks. Prior to inoculation the 'jiffy' pots are allowed to dry out for maximum absorption. Dried 'jiffy' pots are then placed into the inoculum with the desired spore concentration. The 'jiffy' pots are returned to flats and watered. Lids are placed onto trays and sealed to maintain high humidity in the first few days post inoculation. Plants are scored for wilt symptoms approximately 8–10 days post inoculation. Later during infection, the number of plants dying from infection is recorded.

To further characterize the level of disease caused to a specific genotype, a set of oligonucleotide primers are used to amplify a region of 18S rRNA from F. oxysporum. The primers demonstrate little to no homology with *Arabidopsis* RNA. These primers act to indicate the difference in fungal RNA levels as compared to the amount of plant RNA.

It will be appreciated by persons skilled in the art that numerous variations and/or modifications may be made to the invention as shown in the specific embodiments without departing from the spirit or scope of the invention as broadly

described. The present embodiments are, therefore, to be considered in all respects as illustrative and not restrictive.

All publications discussed above are incorporated herein in their entirety.

Any discussion of documents, acts, materials, devices, articles or the like which has been included in the present specification is solely for the purpose of providing a context for the present invention. It is not to be taken as an admission that any or all of these matters form part of the prior art base or were common general knowledge in the field relevant to the present invention as it existed before the priority date of each claim of this application.
